Abstract

This work addresses... The Multidi Objective knapsack programming. The dynamic programming method... The data structure...

1   Introduction

2   The Multiobjective Knapsack Problem

A general multiobjective optimization problem can be described as a vector function f that maps a tuple of n parameters (decision variables) to a tuple of k objectives. Formally:

$$\min/\max \boldsymbol{y} = f(\boldsymbol{x}) = \big(f_1(\boldsymbol{x}), f_2(\boldsymbol{x}), \ldots, f_k(\boldsymbol{x})\big)$$
$$\text{subject to } \boldsymbol{x} = (x_1, x_2, \ldots, x_n) \in X$$

where $\boldsymbol{x}$ is the *decision vector*, X denotes the set of feasible solutions, and $\boldsymbol{y}$ is the *objective vector* where each objective has to be minimized (or maximized).

Considering two decision vectors $\boldsymbol{a}, \boldsymbol{b} \in X$, $\boldsymbol{a}$ is said to *dominate* $\boldsymbol{b}$ if, and only if $\boldsymbol{a}$ is at least as good as $\boldsymbol{b}$ in all objectives and better than $\boldsymbol{b}$ in at least one objective. Formally:

$$\forall i \in \{1, 2, \ldots, k\} : f_i(\boldsymbol{a}) \geq f_i(\boldsymbol{b})$$
$$\exists j \in \{1, 2, \ldots, k\} : f_j(\boldsymbol{a}) > f_j(\boldsymbol{b})$$

A feasible solution $\boldsymbol{a} \in X$ is called *efficient* if its not dominated by any other feasible solution. The set of all efficient solutions of a multiobjective optimization problem is known as *Pareto optimal*. Solving a multiobjective problem consists in giving its Pareto optimal set.

An instance of a multiobjective knapsack problem (MOKP) with k objectives consists of an integer capacity $W > 0$ and n items. Each item i has a

---

positive weight w_i and non negative integer profits $p_i^1, p_i^2, \ldots, p_i^k$. Each profit p_i^k represents the contribution of the i-th item for k-th objective. A solution is represented by a vector $\boldsymbol{x} = (x_1, \ldots, x_n)$ of binary decision variables such that $x_i = 1$ if, and only if item i is included in the solution. A solution is feasible if the total weight included in the knapsack does not exceed its capacity. Formally the definition of the problem is:

$$\max f(\boldsymbol{x}) = \big(f_1(\boldsymbol{x}), f_2(\boldsymbol{x}), \ldots, f_k(\boldsymbol{x})\big)$$
$$\text{subject to } w(\boldsymbol{x}) < W$$
$$x_i \in \{0, 1\} \quad i = 1, \ldots, n$$

where

$$f_j(\boldsymbol{x}) = \sum_{i=1}^{n} v_i^j x_i \quad j = 1, \ldots, k$$
$$w(\boldsymbol{x}) = \sum_{i=1}^{n} w_i x_i$$

The MOKP is considered a $\mathcal{NP}$-Hard problem since it is a generalization of the well-known $0-1$ knapsack problem, in which $k = 1$. It is quite difficult to determine the Pareto optimal set for the MOKP, especially for high dimension instances, in which the solution it self (Pareto optimal set) tends to grow exponentially. Even for the bi-objective case, small problems may prove intractable. For this reason we are interested in developing efficient methods for handling large solution sets, which may bring tractability to previously intractable instances.

3 The Dynamic Programing Algorithm

Paragrafo de introducao da secao, justificando toda a explicacao que segue..

The dynamic programming algorithm consists of n steps. Basically in i-th step the previous set of solution is replicated

[1]

4 The use of data structure

The k-d tree is a type of binary search tree for indexing multidimensional data with simple construction and low space usage. Despite its simplicity it efficiently supports operations like nearest neighbour search and range search [2]. For those reasons k-d tree is widely used on spacial geometry algorithms [7, 3], clustering [5, 4] and graphic rendering algorithms [6].

Like a standard binary search tree, the k-d tree subdivides data at each recursive level of the tree. Unlike a standard binary tree, that users only one key for all levels of the tree, the k-d tree uses k keys and cycles through these keys for successive levels of the tree.

Concerning it's efficiency, it is important to consider the number of dimensions k-d tree is indexing. As a general rule, a k-d tree is suitable for efficiently indexing of n elements if n is much greater than 2^k. Otherwise, when k-d tree are used with high-dimensional data, most of the elements in the tree will be evaluated and the efficiency is no better than exhaustive search [8].

Indexing the solutions and range operations.

Tends to increase the feasibility on problems with higher dimensions.
